

COMMENTS SUBMITTED BY THE TURBINE INLET COOLING ASSOCIATION
BEFORE THE ENVIRONMENTAL PROTECTION AGENCY
ON
111(D) CARBON POLLUTION STANDARDS FOR EXISTING POWER PLANTS
NOVEMBER 7, 2013

Good morning. My name is Benjamin King; I am here representing the Turbine Inlet Cooling Association (“TICA”), a trade association that promotes the development and exchange of knowledge related to turbine inlet cooling, or TIC, for enhancing power generation. Today we commend EPA for taking important steps to reduce greenhouse gas emissions, and we want to highlight the role that turbine inlet cooling technologies can play in achieving these reductions at a relatively low cost.

Turbine inlet cooling technologies can dramatically improve capacity at clean natural gas units, reducing the need for dirtier coal plants. As EPA has noted, natural gas-fired power plants have substantially lower greenhouse gas emissions than coal-fired power plants.¹ However, we are not maximizing the use of these relatively clean units. As temperatures rise, gas turbine units become less productive, losing as much as 20 percent of the system’s rated capacity when temperatures reach 100 degrees, as is shown in the figure accompanying my written comments. In 2011, summer losses accounted for over 33,000 MW in capacity from natural gas systems.² (see table) Most of this loss could be recovered by TIC technologies.

This drop in productivity occurs at precisely the time when electricity demand is at its highest, as a result of high air conditioning use. To meet that high demand, utilities turn to less efficient and higher emitting units to supplement their decreased generation. Turbine inlet cooling technologies address this problem by cooling the air before it enters a combustion turbine system, thereby restoring most of the capacity of the unit and increasing the amount of electricity it can produce. In so doing, TIC technologies restore higher capacity to natural gas turbines, even during the hottest days of summer, eliminating the need to deploy less efficient and higher-emission emitting plants when consumer demand peaks.

Turbine inlet cooling is both cost effective and adequately demonstrated. With installation costs for a variety of TIC technologies ranging from only a few dollars to a few hundred dollars per kilowatt, existing natural gas plants can reduce their emissions by making a relatively modest investment, as shown in Figure 2 of my written comments. By encouraging the use of turbine inlet cooling, EPA can lower the cost of compliance for the Rule. Moreover, TIC technologies can be installed on turbines of virtually any

² U.S. Energy Information Administration (EIA), 2011, “Electric Power Annual,” Table 4.3 (<http://www.eia.gov/electricity/annual/>).

size, and there are currently hundreds of installations across the United States, as shown on the Turbine Inlet Cooling Association's website.³

These benefits will only be realized with a system-wide approach to emission reductions. The Rule is most likely to directly limit carbon emissions from high-emitting power plants. Most natural gas-fired plants will meet any emission limit set under 111(d), thus removing any incentive to install TIC technologies. However, utilities should be encouraged to reduce emissions where it is the simplest and most cost-effective. By allowing states to credit natural gas units for increasing their capacity (thereby reducing the use of higher emitting plants), EPA can support the transition to relatively cleaner natural gas. In other words, the entire power system should be allowed to work together to achieve state emission targets.

EPA should clarify in its emission guidelines that states can trade emission credits across fuel types and allow flexibility for states to achieve emission limits. EPA should clarify that TIC technologies and other supply-side investments at natural gas units are among the options that states may adopt in developing their state equivalency plans. States, in turn, should adopt policies that allow gas units to generate credits for becoming more productive and reducing emissions from the least efficient and dirtiest plants.

In sum, turbine inlet cooling technologies increase the productivity of relatively clean natural gas power plants, and EPA should design a rule that encourages their use.

Thank you.

Supporting Graphics

Figure 1: Enhancement Capabilities of Turbine Inlet Cooling Technologies

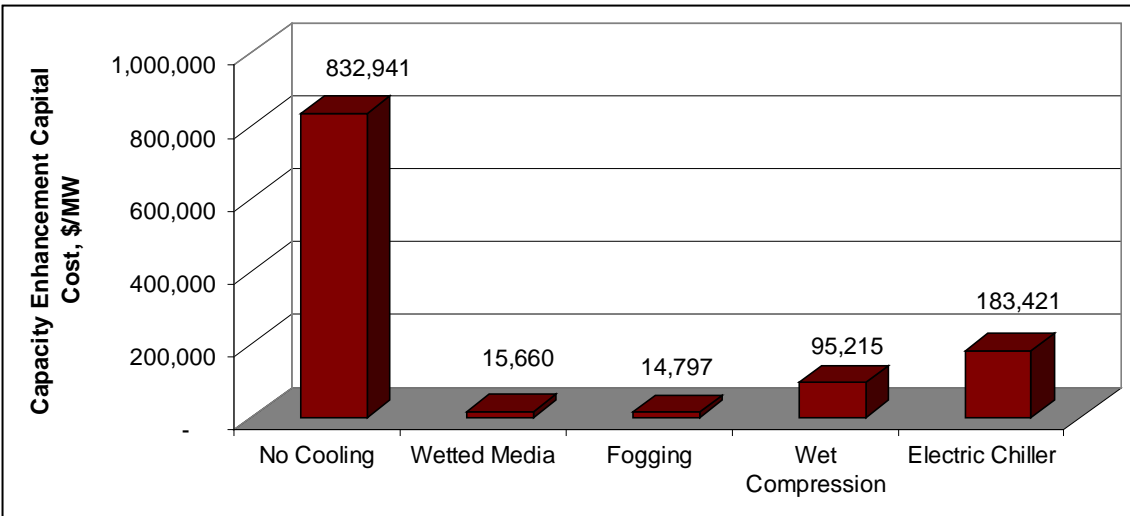

Table 1: U.S. Power Generation Capacity During Winter and Summer (EIA 2011)

Fuel	Winter Capacity, MW	Summer Capacity, MW	Capacity Loss in Summer Relative to Winter, MW
Coal	320,185	317,640	2,545
Petroleum	55,179	51,208	3,971
Natural Gas	448,456	415,191	33,265

Over 33,000 MW of natural gas-fired electric power generation capacity is lost during summer.
